Summary: As of 9:03 am on 3/11/2021, a total of 60,387 cases of laboratory-confirmed COVID-19 among Boston residents have been reported to the Boston Public Health Commission (BPHC). Of reported cases, two thousand seven hundred and eight (4.5%) required hospitalization. One thousand three hundred and one (2.2%) residents have died. Fifty-six thousand nine hundred and twenty-five (94.3%) residents have recovered.

Four thousand and fifteen (6.7%) were healthcare workers.

Emergency Department (ED) visits for COVID-19-like illness (CLI) comprised 3.5% of all ED visits between (3/5 - 3/11/2021), down from 3.8% the prior week.

New daily cases are defined by the date of their first reported positive test. Prior to October 8, 2020, new cases were reported using the event date. An event date is the earliest associated date corresponding to each disease event and is hierarchical based on available information (e.g., symptom onset date, test date, report date).

COVID-19-like illness (CLI) is defined as "Covid or (fever and (cough or respiratory distress))" in ED chief complaint data from Boston acute care hospitals, captured by BPHC Syndromic Surveillance System.

---

**Figure 1. Reported COVID-19 Cases and % CLI Emergency Department Visits, by Week, 2020-2021**

Data Sources: Boston Syndromic Surveillance System (Jan 3, 2020 to Mar 11, 2021); Massachusetts Department of Public Health, Massachusetts Virtual Epidemiologic Network (Jan 3, 2020 to Mar 11, 2021, 9:03 am)

---

§§ %CLI ED (All Visits) is a percentage of CLI visits among all ED including irrespective of residence. %CLI ED (Boston Resident Visits Only) is a percentage of CLI visits by Boston residents among all ED visits by Boston residents.

---

§§ New daily cases are defined by the date of their first reported positive test. Prior to October 8, 2020, new cases were reported using the event date. An event date is the earliest associated date corresponding to each disease event and is hierarchical based on available information (e.g., symptom onset date, test date, report date).
Figure 2: Percent of All COVID-19 Cases (Boston Residents), by Sex, 2020-2021

DATA SOURCES: Massachusetts Department of Public Health, Massachusetts Virtual Epidemiologic Network (Jan 1, 2020 to Mar 11, 2021, 9:03 am)

There was a similar distribution of male cases and female cases (Figure 2). The incidence rate of COVID-19 among female residents was similar compared to male residents (Figure 3). Note: The overall rate was higher than rates by sex due to the 0.6% of cases with other/unknown sex or who identify as transgender.

DATA SOURCES: Massachusetts Department of Public Health, Massachusetts Virtual Epidemiologic Network (Jan 1, 2020 to Mar 11, 2021, 9:03 am); U.S. Census Bureau, American Community Survey, 2018 5-yr estimates (2014-2018)
There continued to be a low percentage of Boston resident COVID-19 cases under 20 years of age (Figure 4). Rates are lowest for those ages 20 years or less, and highest for those ages 80 and above (Figure 5).
The incidence rate of COVID-19 was higher for Dorchester (02121, 02125), Dorchester (02122, 02124), East Boston, Hyde Park, Roslindale, Roxbury, and South Boston compared with the rest of Boston. The incidence rate of COVID-19 was lower for Allston/Brighton, Back Bay (including Beacon Hill, Downtown, the North End, and the West End), Charlestown, Fenway, Jamaica Plain, Mattapan, South End, and West Roxbury compared with the rest of Boston (Figure 6). To test neighborhood differences, an individual neighborhood is compared with the rest of Boston (i.e., all other neighborhoods combined), rather than to Boston overall so that individual neighborhood’s contribution to the Boston overall rate does not mask a difference from the rest of Boston.
Of cases where race/ethnicity was known, 5.9% were Asian, 24.3% were Black, 30.2% were Latinx or Hispanic, 32.8% were White, and 6.7% identified as multi-racial, another racial/ethnic group or Other race. When the percent of information that is missing or unknown is greater than 20%, percentages are calculated among the known cases, but both are presented here.

The incidence rate of COVID-19 was higher for Black and Latinx/Hispanic residents and residents of other races/ethnicities (including multiple races and individuals that did not specify a given race or ethnicity category) compared with the rate for White residents (Figure 7). The incidence rate was lower for Asian residents compared with White residents (Figure 7). Interpret these rates with caution due to the high percentage of missing race/ethnicity data (Table 1).
